

AEGIS

AI Emergency Grid & Incident System

Every phone in the crowd becomes a sensor. Every second becomes coordinated action.

PROJECT TITLE

AEGIS — AI Emergency Grid & Incident System

TEAM

Ninja Coders

EVENT

Cognitive Chaos 2026

TRACK

Convex — Open Innovation (self-proposed problem)

PROBLEM STATEMENT

Emergencies at mass gatherings unfold in seconds, but incident information is scattered, duplicated and unverified, and dispatch is manual — wasting the 5 to 10 minute window in which a crush or cardiac arrest is still survivable.

TEAM MEMBERS

Sourav Kumar · Manish Joshi · Siddharth Singh · Rajat Kushwaha

A real-time web platform — nothing to install

In a crowd, the tools we rely on are the tools that fail

121

lives lost, Hathras stampede, 2024

11

lives lost, RCB victory crowd, Bengaluru stadium, 2025

5-10

minutes — the survivable window in a crush or cardiac arrest

0

shared live picture of the venue at any of these events

Police, medics and fire were already on site every time. What was missing was information, not manpower.

WHY CALLING FOR HELP DOES NOT WORK IN A CROWD

You cannot hear, and cannot be heard. A crowd runs past 100 dB. The control room mishears the location — the one detail that matters.

The cell network is congested. Thousands of phones on one tower means voice calls drop exactly when everyone needs them at once.

Nobody knows the number. The venue control room number is not on your ticket, and 112 cannot see inside the venue.

A call carries one report, once. Thirty callers about one crush create thirty conversations, not one prioritised incident.

WHO IS AFFECTED, AND WHAT THEY HAVE TODAY

Attendees — no way to report that works in noise and congestion.

Marshals and volunteers — first to see it, no channel to escalate.

Medics, fire and police — on site, but sent by guesswork.

Organisers and administration — own the liability, see fragments.

Current solution: walkie-talkies and WhatsApp groups.

No single live picture — every channel sees a fragment. Duplicate, unverified reports with no way to merge them. No severity triage, so a lost phone and a cardiac arrest arrive identical. Manual dispatch spends minutes working out who is nearest. No audit trail to learn from.

One tap replaces the call that cannot get through

AEGIS is a live emergency response system for crowded places. Anyone reports in **one tap** — no login, no OTP, no typing and no speaking. A tap is a few hundred bytes, so it gets through congested networks where a voice call will not. An AI scores how serious it is, merges duplicate reports of the same event into one incident, and retrieves the correct response steps from **real NDMA government guidance**. A control room dashboard dispatches the nearest right-role unit in one click, and the person who reported it watches help approach with a live ETA.

01 REPORT

One tap sends it, with GPS attached automatically. Photo, description and a callback number are optional and offered afterwards — help is already moving while you add them.

02 AI TRIAGE

The AI scores severity P1–P4, writes an operator summary, merges duplicates, and retrieves protocol steps from real NDMA and Red Cross guidance by meaning, not keyword.

03 COORDINATE

The nearest role-matched unit is dispatched in one click. The reporter sees a live ETA. Every action is written to an immutable audit timeline.

WHAT MAKES IT DIFFERENT

The advice is traceable to a government document, never invented — and the system **degrades instead of failing**: if the AI is unavailable it falls back to deterministic rules and says so on screen, while still triaging and dispatching.

Report in one tap

NDMA guidance, sourced

EnterPro front end, Convex back end, one AI brain

What we will show you live, in this order

The dashboard starts empty. Everything you see appear is filed live, from a phone in this room.

Command dashboard — live venue map, incident queue, AI panel, NDMA actions, reporter callback and photo evidence

- 1 REPORTER — a teammate files a real emergency**
Opens the public link, taps SOS, taps Fire. One tap, no login. GPS places it at the Food Court automatically.
- 2 COMMAND — it appears in about one second**
AI has scored it P1 Critical, written the summary and retrieved the fire protocol from NDMA guidance, with the source shown.
- 3 COMMAND — duplicate merge, then dispatch**
A second report of the same fire merges into one incident with a count of two. One click dispatches the nearest fire unit.
- 4 RESPONDER — accept, then broadcast**
The unit accepts on a second phone; the reporter's screen flips to a live ETA. We broadcast exit guidance to every phone.

WE WILL SAY THIS BEFORE YOU ASK

Reporting, triage, merging, dispatch and tracking are all real and running. Venue responders are **simulated** for this demo, not live staff. Location is device GPS only, never from a phone number.

Six capabilities, and what makes each one hard to copy

01 Live command map

Every report appears on every dashboard the instant it is filed — one shared source of truth for the venue.

Convex reactive queries are live subscriptions

02 AI triage and de-duplication

Severity scored by the LLM; reports of the same event, same zone, within 120 seconds merge into one counted incident.

Actions call the model, mutations write the result

03 Protocol-grounded response

Steps retrieved from real NDMA guidance by meaning, with the source document named on screen.

Convex vector search over the protocol table

04 Role-matched dispatch

The nearest correct unit in one click — a medic for medical, a fire unit for fire. Unacknowledged P1 escalates in 60 s.

Scheduler functions and indexed queries

05 Live responder tracking

The reporter watches the assigned unit approach with a live ETA, the way you track a delivery.

Location updates through the reactive database

06 Evidence and audit trail

Photograph, callback number and an immutable timestamped timeline for every incident.

File storage plus an append-only event log

WHAT ACTUALLY SETS US APART

1. The AI cannot invent procedure. It searches real NDMA and Red Cross documents first and may only compose steps from what it retrieved — the source is printed on screen. **2. It degrades instead of failing.** If the AI is rate-limited we fall through three models, then to deterministic rules, and the dashboard says so openly. **3. Panic becomes signal.** Thirty reports of one crush become one P1 incident with a count of thirty. **4. The venue is data, not code.** One record re-points AEGIS from a campus to Jantar Mantar or a stadium, switchable live from the dashboard.

Minutes saved are lives saved — and it runs today for almost nothing

3

venues live across two states,
switchable from the dashboard

14

real NDMA and Red Cross protocols
grounding every recommendation

Rs 0

infrastructure cost at pilot scale —
free tiers, no servers to run

1 tap

for any citizen to summon a
role-matched responder

WHO BENEFITS

Every attendee — nothing to install, it is a web link.

Marshals and volunteers — a channel that works in noise.

Medics, fire and police — sent to the right spot, first time.

Organisers and district administration — one live picture, and an audit trail afterwards.

Beyond event venues this extends directly to campuses, religious gatherings, railway stations, hospitals and industrial sites — anywhere crowds and risk meet.

WHY IT IS REALISTICALLY DEPLOYABLE

No app store, no install. A venue prints a QR code; anyone with a browser can report.

The venue is a data record. Zones, exits and responding units — a new site needs no code change.

Serverless throughout. Convex scales with crowd size and the front end is static. We load-tested 50 simultaneous reports with zero failures; capacity is not our bottleneck, it is a platform concern.

Costs nothing to pilot. A district could run this for a festival on free tiers.

HONEST LIMITS — WE STATE THESE OURSELVES

Venue responders are **simulated** for this demo, not live staff. There is **no AI verification of photographs** yet — the image is shown to the operator for human judgement. **Offline queueing is designed but not implemented**, so a report needs a moment of connectivity. The operator login gates the screen rather than the API; production uses role-scoped authentication. Facility coordinates in our alternate venues are real institutions at approximate positions, not a verified government feed.

What we build next, and who built this

WHAT COMES NEXT

Voice reporting

Speak instead of tapping, for anyone who cannot type or see the screen in an emergency.

Crowd-density warning

Read density from CCTV and warn before the crush, not after.

Offline-first reporting

Queue the report on the device and sync the moment signal returns.

Verified facility data

Ingest the government facility directory for real hospital, police and fire locations nationwide.

AI photo verification

Flag reports whose image does not match the reported category.

Open-source release

So any district administration or college can run it — cost should never be why a crowd has no system.

TEAM NINJA CODERS

Sourav Kumar

Team lead — EnterPro front end, design system, pitch and live demo

Siddharth Singh

Convex data core — schema, de-duplication, dispatch and escalation logic

Rajat Kushwaha

AI triage and retrieval — LLM prompting, protocol grounding, fallback chain

Manish Joshi

Integration, deployment and testing — EnterPro to Convex bridge, load and failure testing

TRY IT YOURSELF, RIGHT NOW

Open it on your own phone and file a report. It appears on our dashboard in about a second.
